Danfoss

Compressor model designation

Danfoss scroll compressors are available both as single compressors and as tandem units. The example below presents the single compressor nomenclature which equals the technical reference as shown on the compressor nameplate.

Code numbers for ordering list are section "Ordering information & packaging".

For tandem and trio assemblies, please refer to the Danfoss Parallel Application Guidelines documentation FRCC.PC.005.

SY380: 380-400V/3~/60 Hz

* When SM compressors are used with R417A, the factory charged mineral oil 160P must be replaced by polyolester oil 160SZ

**Only motor voltage 4 are qualified with R513A

ant

Danfoss scroll compression principle

In a Danfoss SM / SY / SZ scroll compressor, the compression is performed by two scroll elements located in the upper part of the compressor.

Suction gas enters the compressor at the suction connection. As all of the gas flows around and through the electrical motor, thus ensuring complete motor cooling in all applications, oil droplets separate and fall into the oil sump. After exiting the electrical motor, the gas enters the scroll elements where compression takes place. Ultimately, the discharge gas leaves the compressor at the discharge connection.

The figure below illustrates the entire compression process. The centre of the orbiting scroll (in grey) traces a circular path around the centre of the fixed scroll (in black). This movement creates symmetrical compression pockets between the two scroll elements. Low-pressure suction gas is trapped within each crescent-shaped pocket as it gets formed; continuous motion of the orbiting scroll serves to seal the pocket, which decreases in volume as the pocket moves towards the centre of the scroll set increasing the gas pressure. Maximum compression is achieved once a pocket reaches the centre where the discharge port is located; this stage occurs after three complete orbits. Compression is a continuous process: the scroll movement is suction, compression and discharge all at the same time.

SM SY SZ 084-090-100-110-120-148-161-175-185-240-300-380

antos

In addition to the existing SM range compressors previously available, Danfoss is completing its range with 3 compressors.

The new SM112-124-147 and SZ147 compressors benefit from a further improved design to achieve the highest efficiency.

Gas circulation, motor cooling and oil behaviour are improved by a new patented motor cap design. Part protection and assembly reduces internal leaks and increases life durability.

Improved part isolation reduces greatly acoustic levels.

Gas intake design induces higher resistance to liquid slugging.

SM112-124-147 and SZ147

Oil sight glass	All Danfoss SM / SY / SZ scroll compressors come equipped with a sight glass (1"1/8-18 UNEF) which may be used to determine the amount and condition of the oil contained within the sump.	Oil fill connection and gauge port
Oil equalisation connection	SM/SZ 112-124-147: 1"3/4 rotolock connector allowing use of 1"3/4-7/8" or 1"3/4-1"1/8 SY 240-300-380: 1/2" flare Other models: 3/8" flare This connection must be used to mount an oil equalisation line when two or more compressors are mounted in parallel (please refer to Danfoss Parallel Application Guidelines reference FRCC.PC.005 for details).	
Oil drain connection	The oil drain connection allows oil to be removed from the sump for changing, testing, etc. The fitting contains an extension tube into the oil sump to more effectively remove the oil. The connection is a female 1/4" flare fitting. Note : on SY240 to 380, it is not possible to drain oil from the suction connection.	Oil sightOil drain glass connection
Schrader	The oil fill connection and gauge port is a 1/4" male flare connector incorporating a schrader valve.

* SY 380

Wiring connections

Electrical power is connected to the compressor terminals by Ø 3/16" (4.8 mm) screws. The maximum tightening torque is 2.2ft.lb. Use a 1/4" ring terminal on the power leads.

SM / SZ 084 - 090 - 100 - 110 - 112 - 120 - 124 - 147* -148* - 161*

*Except for motor voltage code 3

The terminal box is provided with a Ø 1" and a Ø 1.14" knockouts.

SM/SZ 147 code 3

The terminal box is provided with a Ø 1.59" hole for power supply and a Ø 0.65" knockout.

Danfoss

Application guidelines	Electrical data, connections and wiring	
SY 240 – 300 – 380 & SM/SZ 185 - P, X, Y versions	 The terminal box is provided with 2 triple knockouts and 1 single knockout for power supply and 4 double knockouts for the safety control circuit. The 3 power supply knockouts accommodate the following diameters: Ø 2 inch (UL 1"1/2 conduit) & Ø 1.72 inch (UL 1"1/4 conduit) & Ø 1.36 inch (UL 1" conduit) Ø 1.59 inch (ISO40) & Ø 1.27 inch (ISO32) & Ø 1 inch (ISO25) Ø 1 inch (ISO25) The 4 others knockouts are as follows: Ø 0.89 inch (PG16) (UL 1/2") & Ø 0.65 inch (ISO16) (x2) 0.81 inch (ISO20 or PG13.5) (x2) 	Black Brown UL213 UL213 WI - M2 Control circuit Module power supply Faston 1/4" tabs
	The motor protection module comes preinstalled within the terminal box. Phase sequence protection connections and thermistor connections are pre-wired. The module must be connected to a power supply of the appropriate voltage. The module terminals are 0.25" size Faston type.	Phase sequence input Phase sequence input Internal control contact Black Blue Brown I N S1 S2 M1 M2 Safety Circuit Module power
IP rating	 The compressor terminal box according to IEC529 i cable glands are used. First numeral, level of protection against contact 5 - Dust protected Second numeral, level of protection against water 4 - Protection against water splashing. 	and foreign objects
Terminal box temperature	The temperature inside the terminal box may not exceed 158°F. Consequently, if the compressor is installed in an enclosure, precautions must be taken to avoid that the temperature around the compressor and in the terminal box would rise too much. The installation of ventilation on the enclosure panels may be necessary. If not, the	electronic protection module may not operate properly. Any compressor damage related to this will not be covered by Danfoss warranty. In the same manner, cables must be selected in a way to insure that terminal box temperature does not exceed 158°F.

<u>Danfošš</u>

Application guidelines	Electrical data, connections a	and wiring			
LRA (Locked Rotor Amp)	Locked Rotor Amp value is the higher current as measured on mechanically blocked compressor tested under nominal voltage. The LRA value can be used as rough estimation for the starting		current. However in most cases, the real starting current will be lower. A soft starter can be applie to reduce starting current.		
MMT (Max Must Trip current)	The MMT is defined for compressors without their own motor protection. This MMT value is the maximum at which the compressor can be operated in transient conditions and out of the application envelope. The tripping current		of external overcurrent protection (thermal overload relay or circuit breaker not provide with compressor) must never exceed the MI value.		
MCC (Maximum Continuous Current)	The MCC is the current at which the protection trips under maximum low voltage conditions. This MCC waximum at which the compressed operated in transient conditions a	load andinternal motor protection or external electronvalue is themodule will cut-out the compressor to protector can bethe motor.		protection or external electronic	
Max. operating Current	The max. operating current is the current when the compressors operates at maximum load conditions and 10% below the highest value of its nominal voltage (59°F evaporating temperature and 154.4°F condensing temperature).		Max Oper. A can be used to select cables and contactors. In normal operation, the compressor current consumption is always less than the Max Oper. A value.		
Winding resistance	Winding resistance is the resistance between indicated terminal pins at 77°F (resistance value +/- 7%). Winding resistance is generally low and it requires adapted tools for precise measurement. Use a digital ohm-meter, a "4 wires" method and measure under stabilised ambient temperature. Winding resistance varies strongly with winding temperature ; if the compressor is stabilised at a different value than 77°F, the measured resistance must be corrected with following formula:			sistance at t _{amb}	
Danfoss MCI soft-start controller	The inrush current for the Danfoss compressors with motor code 4 (4 or 460V / 3 / 60Hz) can be reduced Danfoss digitally-controlled MCI co starter. Application guidelines	Electrical data, connections and wiring		
Input controlled soft start	When the control voltage is applied to A1 - A2, the MCI soft starter will start the motor, according to the settings of the ramp-up time and initial torque adjustments. When the control voltage is switched OFF, the motor will switch off instantaneously.	MCI 1/L1 3/L2 5/L3 CTI MCI 1/L1 3/L2 5/L3 0 10 12 JAC JAC JAC JAC JAC JAC JAC JAC JAC JAC	
MCI with bypass contactor	By means of the built-in auxiliary contact (23-24) the bypass function is easily achieved, see wiring diagram below.		
	No heat is generated from the MCI. As the contactor always switches in no-load condition it can be selected on the basis of the thermal current (AC-1).		
	13-14 contact not applicable with MCI 25C		
General wiring information	The wiring diagrams below are examples for a safe and reliable compressor wiring. In case an alternative wiring logic is chosen, it's imperative to respect the following rules. When a safety switch trips, the compressor must stop immediately and must not re-start until the tripping condition is back to normal and the safety switch is closed again. This applies to the LP safety switch, the HP safety switch, the discharge gas thermostat and the motor safety thermostat. In specific situations, such as winter start operation, an eventual LP control for pump- down cycles may be temporarily bypassed to	allow the system to build pressure. But it remain mandatory for compressor protection to apply a LP safety switch. The LP safety switch must never be bypassed. Pressure settings for the LP and HP safety switch and pump-down are indicated section "Operatin conditions". When ever possible (ie. PLC control), it is recommended to limit the possibilities of compressor auto restart to less than 3 to 5 times during a period of 12 hours when caused by motor protection or LP safety switch tripping. This control must be managed as a manual reset device.

	REC Recommended	REQ Required	Vo t	est or additional safeties required

Compressor models SM/SZ084 - 090 - 100 - 110 - 112 - 120 - 124 - 147 - 148 - 161 have been provided with an internal overload motor protection to prevent against excessive current and temperature caused by overloading, low refrigerant flow phase loss or incorrect motor rotation. The cutout current is the MCC value listed in section "Three phase electrical characteristics". The protector is located in the star point of the motor and, should it be activated, will cut out all three phases. It will be reset automatically.	 While not compulsory, an additional external overload protection is still advisable for either alarm or manual reset. Then it must be set below MCC value (at max operating current): when the motor temperature is too high, then the internal protector will trip when the current is too high the external overload protection will trip before the interna protection therefore offering possibility of manual reset.
Compressor models SM/SZ175 - 185 R & C versions have been provided with a bimetallic single-pole, single-throw thermostat located	A circuit breaker, on the other hand, should be set at not more than 125% of the compressor rated load current.
in the motor windings. In the event of motor overheating caused by low refrigerant flow or improper motor rotation, the thermostat will open. Because the thermostat is an automatic	The rated load current is the maximum current expected during operations of the considered application.
reset device, it must be wired within a lockout safety circuit with a manual reset to restart the	Further requirements for the external overload protector are:
unit. For over-current and phase loss protection, an external overload protector must be used.	• Over-current protection : the protector must trip within 2 minutes at 110% of the Maximum Must-Trip current (MMT).
The external overload protector can be either a thermal overload relay or a circuit breaker:	• Locked rotor protection : the protector must trip within 10 seconds upon starting at a locked rotor current (LRA).
A thermal overload relay should be set to trip at not more than 140% of the compressor-rated load current.	• Single-phasing protection: the protector must trip when one of the three phases fails.
Compressor models SY 240 - 300 - 380 and SM/SZ 185 P, X, Y versions are delivered with a pre-installed motor protection module inside the terminal box. This device provides for efficient and reliable protection against overheating and overloading (as well as phase loss/reversal.	The motor protector comprises a control module and PTC sensors embedded in the motor winding. The close contact between thermistors and windings ensures a very low level of therma inertia.
	The motor temperature is being constantly measured by a PTC thermistor loop connected

on S1-S2.

Danfoss

Application guidelines	Electrical data, connections and wiring				
	If any thermistor exceeds its response temperature, its resistance increases above the trip level (4,500 Ω) and the output relay then trips -ie. contacts M1-M2 are open. After cooling to below the response temperature (resistance < 2,750 Ω), a 5 minute time delay is activated. After this delay has elapsed, the relay is once again pulled in ie. contacts M1-M2 are closed. The time delay may be cancelled by means of resetting the mains (L-N disconnect) for approximately 5 sec. A red/green twin LED is visible on the module. A solid green LED denotes a fault free condition.	A blinking red LED indicates an identifiable fault condition: PTC overheat			
Phase sequence and reverse rotation protection	Use a phase meter to establish the phase orders and connect line phases L1, L2 and L3 to terminals T1, T2 and T3, respectively. The compressor will only operate properly in a single	direction, and the motor is wound so that if the connections are correct, the rotation will also be correct.			
	Compressor model SM112-124-147 have no internal reverse rotation protection. If reverse rotation occurs it will be obvious as soon as power is turned on. The compressor will not build-up any pressure, the sound level will be abnormally high and power consumption will be minimal. In such case, shut down the compressor	immediately and connect the phases to their proper terminals. Prolonged reverse rotation will damage the compressor.			
	Compressor models SM / SZ 084 to 185 (except SM112-124 & 147) incorporate an internal reverse vent valve which will react in the presence of reverse rotation and will allow refrigerant to circulate through a by-pass from the suction to the discharge. Although reverse rotation is not destructive, even over long periods of time up to several days it should be corrected as soon as possible. Reverse rotation will be obvious	to the user as soon as power is turned on; the compressor will not build up any pressure, the sound level will be abnormally high and power consumption will be minimal. If reverse rotation symptoms occur, shut the compressor down and connect the phases to their proper terminals. If reverse rotation is not halted, the compressor will cycle off on the internal motor protection.			

antosa

Electrical data, connections and wiring

Compressor models SY240 to SY380 are

delivered with an electronic module which provides protection against phase reversal and loss at start-up. Apply the recommended wiring diagrams. The circuit should be thoroughly checked in order to determine the cause of the phase problem before re-energizing the control circuit.

The phase sequencing and phase loss monitoring functions are active during a 5 sec. window 1 sec. after compressor start-up (power on L1-L2-L3).

Should one of these parameters be incorrect, the relay would lock out (contact M1-M2 open). The red led on the module will show the following blink code:

In case of phase reverse error:

In case of phase loss error:

The lockout may be cancelled by resetting the power mains (disconnect L-N) for approximately 5 sec.

Voltage unbalance

The operating voltage limits are shown in the table section "Motor voltage". The voltage applied to the motor terminals must lie within these table limits during both start-up and normal operations. The maximum allowable voltage

unbalance is 2%. Voltage unbalance causes high amperage over one or several phases, which in turn leads to overheating and possible motor damage. Voltage unbalance is given by the formula:

% voltage	Vavg - V1-2 + Vavg - V1-3 + Vavg - V2-3	x 100	
unbalance =	2 x Vavg

Application guidelines	Operating conditions	
	The scroll compressor application range is influenced by several parameters which need to be monitored for a safe and reliable operation. These parameters and the main recommendations for good practice and safety devices are explained hereunder.	 Refrigerant and lubricants Motor supply Compressor ambient temperature Application envelope (evaporating temperature, condensing temperature, return gas temperature)
Refrigerant and lubricants General information	 When choosing a refrigerant, different aspects must be taken into consideration: Legislation (now and in the future) Safety Application envelope in relation to expected running conditions Compressor capacity and efficiency Compressor manufacturer recommendations & guidelines 	Additional points could influence the final choice • Environmental considerations • Standardisation of refrigerants and lubricants • Refrigerant cost • Refrigerant availability
R22	R22 is an HCFC refrigerant and is still a wide use today. It has a low ODP (Ozone Depletion Potential). Starting from 1st January 2010, the use of virgin R22 refrigerant is no longer allowed in the European Union. Refer to FRCC.EN.049 for R22 retrofit recommendations.	When R22 is applied in refrigeration applications it can lead to high discharge temperature. Carefully check all other parameters that can influence the discharge temperature.
R407C	R407C is an HFC refrigerant and has a zero ozone depletion potential (ODP=0) R407C is a zeotropic mixture and has a temperature glide of 45.3°F	but has a superior thermodynamic properties compared to R22.
R134a	R134a is an HFC refrigerant and has zero ozone depletion potential (ODP = 0). R134a is a pure refrigerant and has zero temperature glide. For	applications with high evaporating and high condensing temperatures, R134a is the ideal choice.
R513A	R513A is an HFO/HFC Blend, with similar thermodynamic properties to the R134a. R513A is an Azeotrope refrigerant with a negligible	glide. R513A has zero ozone depletion potential (ODP=0) and a Global Warming Potential (AR5) at 573
R404A	R404A is an HFC refrigerant and has zero ozone depletion potential (ODP = 0). R404A is especially suitable for low evaporating temperature applications but it can also be applied to medium evaporating temperature applications. R404A is a	mixture and has a very small temperature glide, and therefore must be charged in its liquid phase, but for most other aspects this small glide can be neglected. Because of the small glide, R404A is often called a near-azeotropic mixture.
R507	R507 is an HFC refrigerant with properties comparable to R404A. R507 has no ozone depletion potential (ODP = 0). As with R404A, R507 is particularly suitable for low evaporating	temperature applications but it can also be used for medium evaporating temperature applications. R507 is an azeotropic mixture with no temperature glide.
Mineral oil	Mineral oil can be applied in system using HCFC's refrigerant because it has a good miscibility with HCFC and oil that leave the compressor with refrigerant may not be trapped in lines or	exchangers. The chlorine contained in HCFC's improves lubricity in bearings used with mineral oil. Mineral oil has a very low hygroscopicity but may chemically react with water and form acids.
POE oil	Polyol Ester Oil (POE) is miscible with HFC's (while mineral oil is not), but has to be evaluated regarding lubricate ability in compressors. POE oil has better thermal stability than	refrigerant mineral oil. POE is more hygroscopic and also holds moisture more tightly than mineral oil. It also chemically react with water leading to acid and alcohol formation.

<u>Danfoss</u>

Application guidelines	Operating conditions
Motor supply	SM / SY / SZ scroll compressors can be operated at nominal voltages as indicated on page 18.allowed within the indicated voltage ranges. In case of risk of under-voltage operation, special attention must be paid to current draw.
Compressor ambient temperature	SM / SY / SZ compressors can be appliedas 100 % suction gas cooled without need forfrom -31°F to 145.4°F (for SM/SZ084 to 185)additional fan cooling. Ambient temperature hasand 127.4°F (for SY/SZ 240 to 380) ambientvery little effect on the compressor performancetemperature. The compressors are designedas 100 % suction gas cooled without need for
High ambient temperature	In case of enclosed fitting and high ambient temperature it's recommend to check the temperature of power wires and conformity to their insulation specification.In case of safe tripping by the compressor
Low ambient temperature	Although the compressor itself can withstand low ambient temperature, the system may require specific design features to ensure safeand reliable operation. See section 'Specific application recommendations'.
Application envelope at dew temperatures	The operating envelopes for SM / SY / SZThe operating limits serve to define the envelope within which reliable operations of the compressor are guaranteed: • Maximum discharge gas temperature: 275°F

SY240 to 380

R407C

Application envelopes at mean temperatures

Refrigerant R407C is a zeotropic mixture, which causes a temperature glide in both the evaporator and condenser. When discussing evaporating and condensing temperatures therefore, it is important to indicate whether these are DEW point values or MEAN point values. In the figure below, the dashed lines reflect constant temperature and do not correspond with the constant pressure lines. For a given cycle, the MEAN point temperatures are typically about 3.5° to 5.4°F lower than DEW point temperatures. In these Selection and Application Guidelines, Danfoss Commercial Compressors displays temperatures as DEW point values.

The performance tables for R407C are also based on DEW point values.

The following operating diagrams show the difference between mean and dew temperature application envelopes.

Mean temperature

Example for SZ 084 to 185

Operating conditions

Discharge temperature protection

The discharge gas temperature must not exceed 275°F. The discharge gas thermostat accessory kit (code 7750009) includes all components required for installation, as shown below. The thermostat must be attached to the discharge line within 150 mm from the compressor discharge port and must be thermally insulated and highly fixed on the pipe.

DGT protection is required if the high and low pressure switch settings do not protect the compressor against operations beyond its specific application envelope. Please refer to the examples on following page, which illustrates where DGT protection is required (ex.1) and where it is not (ex.2).

A discharge temperature protection device must be installed on all heat pumps. In reversible air-to-air and air-to-water heat pumps the discharge temperature must be monitored during development test by the equipment manufacturer.

The DGT should be set to open at a discharge gas temperature of 275°F.

The compressor must not be allowed to cycle on the discharge gas thermostat. Continuous operations beyond the compressor's operating range will cause serious damage to the compressor.

anto

Internal pressure relief valve

Operating conditions

The SY240 to SY380 incorporate an internal relief valve set to open between the internal high and low pressure sides of the compressor when the pressure differential between the discharge and suction pressures surpasses 450 to 551 psi.

This safety feature prevents the compressor from developing dangerously high pressures should the high pressure cutout, for whatever reason, fail to shut down the compressor.

Low pressure

A low pressure (LP) safety switch must be used. Deep vacuum operations of a scroll compressor can cause internal electrical arcing and scroll instability. Danfoss scroll compressors exhibit high volumetric efficiency and may draw very low vacuum levels, which could induce such a problem. The minimum low-pressure safety switch (loss of charge safety switch) setting is

given in the following table. For systems without pump-down, the LP safety switch must either be a manual lockout device or an automatic switch wired into an electrical lockout circuit. The LP switch tolerance must not allow for vacuum operations of the compressor. LP switch settings for pump-down cycles with automatic reset are also listed in the table below.

	R22 psig	R407C psig	R134a psig	R404A/R507A psig	R513A psig
Working pressure range high side	158 - 401	152 - 422	97 - 292	184 - 451	74 - 303
Working pressure range low side	20 - 100	15 - 92	8 - 56	29 - 106	12 - 62
Maximum high pressure safety switch setting	406	427	297	457	323
Minimum low pressure safety switch setting *	7	7	7	7	7
Minimum low pressure pump-down switch setting **	18	14	7	26	9

*LP safety switch shall never be bypassed and shall have no time delay. **Recommended pump-down switch settings: 1.5 bar (R22, R407C, R404A) or 1 bar (R134a) below nominal evaporating pressure.

recommended.

Note that these two different low pressure switches also require different settings. The low pressure pump down switch setting must always be within the operating envelope, for example 13 psi for R22. The compressor can be operated

full time under such condition. The minimum low pressure safety switch setting may be outside the normal operating envelope and should only be reached in exceptional (emergency) situations, for example 7 psi for R22.

Cycle rate limit

Danfoss recommends a restart delay timer to limit compressor cycling. The timer prevents reverse compressor rotation, which may occur during brief power interruptions.

The system must be designed in a way that guarantees a minimum compressor running time of 2 minutes so as to provide for sufficient motor cooling after start-up along with proper oil return. Note that the oil return may vary since it depends upon system design.

There must be no more than 12 starts per hour (6 when a resistor soft-start accessory is introduced); a number higher than 12 reduces the service life of the motor-compressor unit. If necessary, place an anti-short-cycle timer in the control circuit, connected as shown in the wiring diagram section "Suggested wiring diagrams logic". A three-minute (180-sec) time out is

Please contact Danfoss Technical Support for any deviation from this guidelines.

Application guidelines	System design recommendations	
General	Successful application of scroll compressors is dependent on careful selection of the compressor for the application. If the compressor is not correct for the system, it will operate	beyond the limits given in this manual. Poor performance, reduced reliability, or both may result.
Essential piping design considerations	Proper piping practices should be employed to ensure adequate oil return, even under minimum load conditions with special consideration given to the size and slope of the tubing coming from the evaporator. Tubing returns from the evaporator should be designed so as not to trap oil and to prevent oil and refrigerant migration back to the compressor during off-cycles. Piping should be designed with adequate three- dimensional flexibility. It should not be in contact with the surrounding structure, unless a proper	tubing mount has been installed. This protection proves necessary to avoid excess vibration, which can ultimately result in connection or tube failure due to fatigue or wear from abrasion. Aside from tubing and connection damage, excess vibration may be transmitted to the surrounding structure and generate an unacceptable noise level within that structure as well (for more information on noise and vibration, see the section on: "Sound and vibration management").
Suction lines	If the evaporator lies above the compressor, as is often the case in split or remote condenser systems, the addition of a pump-down cycle is strongly recommended. If a pump-down cycle were to be omitted, the suction line must have a loop at the evaporator outlet to prevent refrigerant from draining into the compressor during off-cycles. If the evaporator were situated below the compressor, the suction riser must be trapped so as to prevent liquid refrigerant from collecting at the outlet of the evaporator while the system is	idle, which would mislead the expansion valve's sensor (thermal bulb) at start-up.
Discharge lines	When the condenser is mounted at a higher position than the compressor, a suitably sized "U"-shaped trap close to the compressor is necessary to prevent oil leaving the compressor from draining back to the discharge side of the compressor during off cycle. The upper loop also helps avoid condensed liquid refrigerant from draining back to the compressor when stopped.	Upper loop UTrap UTrap UTrap UTrap UTrap UD flexibility
Heat exchangers	An evaporator with optimized distributor and circuit will give correct superheat at outlet and optimal use of the exchange surface. This is critical for plate evaporators that have generally a shorter circuit and a lower volume than shell & tubes and air cooled coils. For all evaporator types a special care is required for superheat control leaving the evaporator and oil return.	A sub-cooler circuit in the condenser that creates high sub cooling will increase efficiency at high condensing pressure. Furthermore, for good operation of the expansion device and to maintain good efficiency in the evaporator it is important to have an appropriate sub cooling. Without adequate sub cooling, flash gas will be formed at the expansion device resulting in a high degree of vapor at the expansion device inlet leading to low efficiency.

Danfoss

System design recommendations

Refrigerant charge limit Danfoss SM / SY / SZ compressors can tolerate liquid refrigerant up to a certain extend without major problems. However, excessive liquid refrigerant in the compressor is always unfavorable for service life. Besides, the installation cooling capacity may be reduced because of the evaporation taking place in the compressor and/or the suction line instead of the evaporator. System design must be such that the amount of liquid refrigerant in the compressor is limited. In this respect, follow the guidelines given in the section: "Essential piping design recommendations" in priority. Use the tables below to quickly evaluate the required compressor protection in relation with the system charge and the application.

Off-cycle migration	ff-cycle migration Off-cycle refrigerant migration is likely to occur when the compressor is located at the coldest part of the installation, when the system uses a bleed-type expansion device, or if liquid is allowed to migrate from the evaporator into the compressor sump by gravity. If too much liquid refrigerant accumulates in the sump it will saturate the oil and lead to a flooded start: when the compressor starts running again, the refrigerant evaporates abruptly under the sudo		: e	 A suitable test to evaluate the risk of off-cycle migration is the following: Stabilize the non running system at 41°F ambient temperature, Raise the ambient temperature to 68°F and keep it for 10 minutes, Start the compressor and monitor sump temperature, sight glass indication and sound level. 			
decrease of the bottom shell pressure, causing the oil to foam. In extreme situations, this might result in liquid slugging (liquid entering the scroll elements), which must be avoided as it causes irreversible damage to the compressor.			ht roll	The presence of liquid in the crankcase can be easily detected by checking the sump level through the oil sight glass. Foam in the oil sump indicates a flooded start.			
	(Danfoss SM/SZ/SY scroll compressors can toler occasional flooded starts as long as the total system charge does not exceed the maximum compressor refrigerant charge.			A noisy start, oil loss from the sump and sump rate cool down are indications for migration. Depending on the amount of migration graduate measures shall be taken: • Sump heater • Liquid line solenoid valve • Pump down cycle		

Jantos

System design recommendations

Sump heater

The surface sump heaters are designed to protect the compressor against off cycle migration of refrigerant. When the compressor is idle, the oil temperature in the sump of the compressor must be maintained at no lower than 18°F above the saturation temperature of the refrigerant on the low-pressure side. This requirement ensures that the liquid refrigerant is not accumulating in the sump. A sump heater is only effective if capable of sustaining this level of temperature difference. Tests must be conducted to ensure that the appropriate oil temperature is maintained under all ambient conditions (temperature and wind). However, below 23°F ambient temperature and a wind speed of above 16 ft/sec, we recommend that the heaters be thermally insulated in order to limit the surrounding energy losses.

Since the total system charge may be undefined, a sump heater is recommended on all standalone compressors and split systems. In addition, any system containing a refrigerant charge in excess of the maximum recommended system charge for compressors requires a crankcase heater. A crankcase heater is also required on all reversible cycle applications. The heater must be energized for a minimum of 6 hours before initial start-up (compressor service valves opened) and must remain energized whenever the compressor is off. Provide separate electrical supply for the heaters so that they remain energized even when the machine is out of service (eg. seasonal shutdown).

Sump heater accessories are available from Danfoss (see section "Accessories").

Liquid line solenoid valve (LLSV)

An LLSV may be used to isolate the liquid charge on the condenser side, thereby preventing against charge transfer or excessive migration to the compressor during off-cycles.

Pump-down cycle

A pump-down cycle represents one of the most effective ways to protect against the off-cycle migration of liquid refrigerant. Once the controls has been satisfied, a solenoid valve closes on the condenser outlet. The compressor then pumps the majority of the system charge into the condenser and receiver before the system stops on the low pressure pump-down switch. This step reduces the amount of charge on the low side in order to prevent off-cycle migration. Recommended settings of the low-pressure pump-down switch can be found in the table section "High and low pressure protection". For suggested wiring diagrams, please see section "Suggested wiring diagram logic".

In certain conditions, the discharge valve may not completely seal and result in compressor restarts during pump down applications. An external, non-bleeding check valve may need to be installed. The quantity of refrigerant on the low pressure side of the system can be further reduced by using a pump-down cycle in association with the LLSV.

Tests for pump down cycle approval:

- As the pump-down switch setting is inside the application envelope, tests should be carried out to check unexpected cut-out during transient conditions (ie. defrost – cold starting).
 When unwanted cut-outs occur, the low pressure pump-down switch can be delayed. In this case a low pressure safety switch without any delay timer is mandatory.
- While the thermostat is off, the number of pressure switch resets should be limited to avoid short cycling of the compressor. Use dedicated wiring and an additional relay which allows for one shot pump-down.

The pump-down allows to store all the refrigerant in the high pressure side circuit. On unitary or close-coupled systems, where the system refrigerant charge is expected to be both correct and definable the entire system charge may be

<u>Danfoss</u>

Application guidelines	System design recommendations	
	stored in the condenser during pump-down if all components have been properly sized. Other application needs a liquid receiver to store the refrigerant.	Receiver dimensioning requires special attention. The receiver shall be large enough to contain part of the system refrigerant charge but it shall not be dimensioned too large. A large receiver easily leads to refrigerant overcharging during maintenance operation.
Liquid flood back	During normal operation, refrigerant enters the compressor as a superheated vapor. Liquid flood back occurs when a part of the refrigerant entering the compressor is still in liquid state.	design must be such that repeated and excessive flood back is not possible. A continuous liquid flood back will cause oil
	Danfoss SM/SY/SZ scroll compressors can tolerate occasional liquid flood back. However system	dilution and, in extreme situations lead to lack of lubrication and high rate of oil leaving the compressor.
	Liquid flood back test - Repetitive liquid flood back testing must be carried out under expansion valve threshold operating conditions: a high pressure ratio and minimum evaporator load, along with the measurement of suction	the saturated suction temperature, or should the discharge gas temperature be less than 54°F above the saturated discharge temperature, this indicates liquid flood back.

 a minimum pressure differential of 87 to 102 psi between the suction and discharge pressures to force the orbiting scroll down against the oil film on the thrust bearing. Anything less than this differential and the orbiting scroll can lift up, causing a metal-to-metal contact. It is therefore necessary to maintain sufficient discharge pressure in order to ensure this pressure differential. Care should be taken during low ambient operations when heat removal from air-cooled condensers is greatest and head pressure control may be required for low ambient temperature applications. Operation under low pressure differential may be observed generated by the compressor. It is recommended that the unit be tested and monitored at minimum load and low ambient conditions as well. The following considerations should be taken into account to ensure proper system operating characteristics. Expansion device: The expansion device should be sized to ensure proper system operating flow into the evaporator. An oversized valve may result in erratic control. This consideration is especially important in manifolded units where low load conditions may require the frequent cycling of compressor. This can lead to liquid refrigerant entering the compressor if the expansion device should be taken to the evaporator. An oversized valve may result in erratic control. This consideration is especially important in manifolded units where low load conditions may require the frequent cycling of compressors. This can lead to liquid refrigerant entering the compressor if the expansion valve does not provide stable refrigerant super-heat control under varying loads. The superheat setting of the expansion device The superheat setting of the expansion device 	Low ambient start-up	start-up the pressure in the condenser and, if present, the receiver may be so low that a sufficient pressure differential across the expansion device cannot be developed to properly feed the evaporator. As a result, the compressor may go into a deep vacuum, which can lead to compressor failure due to internal arcing and instability in the scroll members. Under no circumstances should the compressor be allowed to operate under vacuum. The low-pressure control must be set in accordance	happening. Early feeding of the evaporator and management of the discharge pressure could help to attenuate these effects. Low pressure differentials can also cause the expansion device to "hunt" erratically, which might cause surging conditions within the evaporator, with liquid spillover into the compressor. This effect is most pronounced during low load conditions, which frequently
	Low ambient operations	a minimum pressure differential of 87 to 102 psi between the suction and discharge pressures to force the orbiting scroll down against the oil film on the thrust bearing. Anything less than this differential and the orbiting scroll can lift up, causing a metal-to-metal contact. It is therefore necessary to maintain sufficient discharge pressure in order to ensure this pressure differential. Care should be taken during low ambient operations when heat removal from air-cooled condensers is greatest and head pressure control may be required for low ambient temperature applications. Operation under low pressure differential may be observed by a significant increase in the sound power level generated by the compressor. It is recommended that the unit be tested and monitored at minimum load and low ambient conditions as well. The following considerations should be taken into account to ensure proper system operating characteristics. Expansion device: The expansion device should be sized to ensure proper control of the refrigerant flow into the evaporator. An oversized valve may result in erratic control. This consideration is especially important in manifolded units where low load conditions may require the frequent cycling of compressors. This can lead to liquid refrigerant entering the compressor if the expansion valve does not provide stable refrigerant super-heat control under varying loads.	9 °F stable superheat is required. Head pressure control under low ambient conditions: Several possible solutions are available to prevent the risk of compressor to vacuum and low pressure differential between the suction and discharge pressures. In air-cooled machines, cycling the fans with a head pressure controller will ensure that the fans remain off until the condensing pressure has reached a satisfactory level. Variable speed fans can also be used to control the condensing pressure. In water-cooled units, the same can be performed using a water regulator valve that is also operated by head pressure, thereby ensuring that the water valve does not open until the condensing pressure is a satisfactory level. The minimum condensing pressure must be set at the minimum saturated condensing temperature shown in the application envelopes. Under very low ambient conditions, in which testing has revealed that the above procedures might not ensure satisfactory condensing and suction pressures, the use of a head pressure control valve is recommended. Note: This solution requires extra refrigerant charge, which can introduce other problems. A non-return valve in the discharge line is recommended and special care should be taken when designing the discharge line.

A crankcase heater and discharge gas cooling to heating, defrost or low-load short cycles. These transient modes of operation thermostat are required for reversible heat pump may lead to liquid refrigerant carryover (or applications. floodback) or excessively wet refrigerant return conditions. As such, reversible cycle applications The following considerations cover the most require specific precautions for ensuring a long important issues when dealing with common compressor life and satisfactory operating applications. Each application design however characteristics. Regardless of the refrigerant should be thoroughly tested to ensure charge in the system, specific tests for repetitive acceptable operating characteristics.

Application guidelines	Specific application recommendations	
Sump heaters	Sump heaters are mandatory on reversible cycle applications given the high probability of liquid migration back to the compressor sump	during off-cycles due to the outdoor location of most units and operations during low ambient conditions.
Discharge temperature thermostat	Heat pumps frequently utilize high condensing temperatures in order to achieve a sufficient temperature rise in the medium being heated. At the same time, they often require low evaporator pressures to obtain sufficient temperature differentials between the evaporator and the outside temperature. This situation may result	the compressor from excessive temperatures. Operating the compressor at too high discharge temperatures can result in mechanical damage to the compressor as well as thermal degradation of the compressor lubricating oil and a lack of sufficient lubrication.
	in high discharge temperature; as such, it is mandatory that a discharge gas thermostat be installed on the discharge line to protect	The discharge gas thermostat should be set to shut down the compressor in the event discharge gas rises above 275°F.
Discharge line and reversing valve, solenoid valves	The Danfoss SM/SY/SZ scroll compressor is a high volumetric machine and, as such, can rapidly build up pressure in the discharge line if gas in the line becomes obstructed even for a very short period of time which situation may occur with slow-acting reversing valves in heat pumps. Discharge pressures exceeding the operating envelope may result in nuisance high-pressure	position. At the same time, it is important that the selection and sizing of the reversing or 4-way valve ensure that the valve switches quickly enough to prevent against too high discharge pressure and nuisance high-pressure cutouts. Check with the valve manufacturer for optimal sizing and recommended mounting positions.
	switch cutouts and place excess strain on both the bearings and motor. To prevent such occurrences, it is important that a 1-meter minimum discharge line length be	In applications with heat recovery or condenser partialisation, servo piloted solenoid valve has to be properly sized or associated with a second small valve in parallel, in order to avoid quick
	allowed between the compressor discharge port and the reversing valve or any other restriction. This gives sufficient free volume for the discharge gas to collect and to reduce the pressure peak during the time it takes for the valve to change	discharge pressure drops when opening. This phenomenon could lead to hammering effects and create constraints on the non return valve integrated in discharge fitting (SM/SY/SZ180 to 380).
Defrost and reverse cycle	The Danfoss SM/SY/SZ scroll compressor has the ability to withstand a certain amount of liquid refrigerant dynamic slug.	EXV can also be opened when compressors are stopped and before 4 way valve is moving in order to decrease pressure difference. Opening degree and time have to be set in order to keep
	When compressors are installed in parallel, in order to limit liquid amount handled per compressor when beginning and ending defrost,	a minimum pressure difference for 4 way valve moving.
	it is recommended to avoid running part load (keep all compressors running or keep them stopped when moving 4-way valves).	Each application design however should be thoroughly tested to ensure acceptable operating characteristics.
	For further details, please refer to Parallel application guidelines FRCC.PC.005.	

Danfoss

Specific application recommendations	
The use of a suction line accumulator is strongly recommended in reversible cycle applications as a result of the possibility of a substantial quantity	the cycle switches back to a defrost cycle or to normal cooling operations.
of liquid refrigerant remaining in the evaporator, which acts as a condenser during the heating cycle.	Sustained and repeated liquid slugging and floodback can seriously impair the oil's ability to lubricate the compressor bearings. This situation can be observed in wet climates where it is
This liquid refrigerant can then return to the compressor, either flooding the sump with refrigerant or as a dynamic liquid slug when	necessary to frequently defrost the outdoor coil in an air source heat pump. In such cases a suction accumulator becomes mandatory.
Apart from residual moisture in the system after commissioning, water could also enter the refrigeration circuit during operation. Water in the system shall always be avoided. Not only because it can shortly lead to electrical failure, sludge in sump and corrosion but in particular because it can cause serious safety risks. Common causes for water leaks are corrosion and freezing. Corrosion : Materials in the system shall be compliant with water and protocted against	Freezing : When water freezes into ice its volume expands which can damage heat exchanger walls and cause leaks. During off periods water inside heat exchangers could start freezing wher ambient temperature is lower than 32°F. During on periods ice banking could occur when the circuit is running continuously at too low load. Both situations should be avoided by connecting a pressure and thermostat switch in the safety line.

This liquid refrigerant can then return to the compressor, either flooding the sump with refrigerant or as a dynamic liquid slug when Apart from residual moisture in the system after commissioning, water could also enter the refrigeration circuit during operation. Water in the system shall always be avoided. Not only because it can shortly lead to electrical failure, sludge in sump and corrosion but in particular because it can cause serious safety risks. Common causes for water leaks are corrosion and freezing.

Jantoss

Application guidelines Sound and vibration management

During start-up transients it is natural for the compressor sound level to be slightly higher than during normal running. SM / SY / SZ scroll compressors exhibit very little increased start-up transient sound. If a compressor is miswired, the compressor will run in reverse. Reverse

compressor rotation is characterized by an objectionable sound. To correct reverse rotation, disconnect power and switch any two of the three power leads at the unit contactor. Never switch leads at the compressor terminals.

SM / SY / SZ compressors are equipped with a discharge valve which closes at compressor shut down and thus prevents the compressor from running backwards. This reduces the stopping sound to a metallic click caused by the closing valve.	When the pressure difference or gas flow at shut down should be very low, this can delay the discharge valve from closing and lead to a longe noise duration.
Typical sound and vibration in Refrigeration and Air-Conditioning systems encountered by design and service engineers may be broken down into	Mechanical vibrations : These generally extend along the parts of the unit and structure.
the following three source categories.	Gas pulsation : This tends to travel through the cooling medium, i.e. the refrigerant.
Sound radiation: This generally takes an	
airborne path.	The following sections will focus on the causes and methods of mitigation for each of the above sources.
	 discharge valve which closes at compressor shut down and thus prevents the compressor from running backwards. This reduces the stopping sound to a metallic click caused by the closing valve. Sound radiation: This generally takes an

Application guidelines	Sound and vibration management	
Compressor sound radiation	For sound radiating from the compressor, the emission path is airborne and the sound waves are travelling directly from the machine in all directions.	come into direct contact with any non-insulated parts on the walls of the unit. Because of the Danfoss's unique design of a
	The Danfoss SM / SY / SZ scroll compressor is designed to be quiet and the frequency of the sound generated is pushed into the higher ranges, which not only are easier to reduce but also do not generate the penetrating power of lower-frequency sound.	full-suction gas-cooled motor, compressor body insulation across its entire operating range is possible. Acoustic hoods are available from Danfoss Commercial Compressors as accessories. They have been developed to meet specific extra low noise requirement. They incorporate sound proofing materials and offer excellent high and low frequency attenuation. These hoods are
	Use of sound-insulation materials on the inside of unit panels is an effective means of substantially reducing the sound being transmitted to the outside. Ensure that no components capable of transmitting sound / vibration within the unit	quick and easy to install and do not increase the overall size of the compressors to a great extend. Refer to section "Running sound level" for sound attenuation and code numbers.
Mechanical vibrations	Vibration isolation constitutes the primary method for controlling structural vibration. Danfoss SM / SY / SZ scroll compressors are designed to produce minimal vibration during operations. The use of rubber isolators on the compressor base plate or on the frame	mounted compressor be of sufficient mass and stiffness to help dampen any residual vibration potentially transmitted to the frame. For further information on mounting requirements, please refer to the section on mounting assembly.
	of a manifolded unit is very effective in reducing vibration being transmitted from the compressor(s) to the unit. Rubber grommets are supplied with all Danfoss compressors. Once the supplied rubber grommets have been properly mounted, vibration transmitted from the compressor base plate to the unit are held to a strict minimum. In addition, it is extremely important that the frame supporting the	The tubing should be designed so as to both reduce the transmission of vibrations to other structures and withstand vibration without incurring any damage. Tubing should also be designed for three-dimensional flexibility. For more information on piping design, please see the section entitled "Essential piping design considerations".
Gas pulsation	The Danfoss SM / SY / SZ scroll compressor has been designed and tested to ensure that gas pulsation has been optimized for the most commonly encountered air conditioning pressure ratio. On heat pump installations and other installations where the pressure ratio lies beyond the typical range, testing should be conducted	under all expected conditions and operating configurations to ensure that minimum gas pulsation is present. If an unacceptable level is identified, a discharge muffler with the appropriate resonant volume and mass should be installed. This information can be obtained from the component manufacturer.

and between -31°F and 158°F when charged with nitrogen.

A When the compressor is mounted as part of an installation, never use the lift rings on the compressor to lift the installation. The risk is run that the lugs could separate from the compressor or that the compressor could separate from the base frame with extensive damage and possible personal injury as a result.

Never apply force to the terminal box with the intention of moving the compressor, as the force placed upon the terminal box can cause extensive damage to both the box and the components contained inside.

Compressor mounting

Maximum inclination from the vertical plane while operating must not exceed 3 degrees. All compressors come delivered with four rubber mounting grommets and metal sleeve liners that serve to isolate the compressor from the base frame. These grommets must always be used to

Mounting of SM/SZ 084-090-100-110-120-148-161-175-185: the required bolt size is HM8. This bolt must be tightened to a torque of 15 ft.lbs. The bolts and washers are supplied with the assembly kit.

Mounting of SM/SZ 112-124-147: the required bolt size is HM8. This bolt must be tightened to a torque of 11 ft/lbs. The bolt and washers are supplied with the assembly kit. When a surface sump heater is used, it must be applied after grommets are mounted on compressor in order to avoid surface sump heater damage. mount the compressor in single application. These grommets attenuate to a great extent the transmission of compressor vibrations to the base frame. The grommets must be compressed until contact between the flat washer and the steelmounting sleeve is established.

Application guidelines	Installation	
	Mounting of SY 240-300-380: the required bolt size is HM10. The minimum required flat washer outside diameter is 20 ft.lbs. Mounting bolts must be tightened to a torque of 30 ft.lbs. These bolts and washers are not supplied with the compressor. Note: The large flat washer must be positioned in place before shipping the unit with the compressor installed. Note : for parallel assemblies see specific recommen FRCC.PC.005.	Lock washer * HM 10 Bolt * Lock washer * Compressor base plate Steel mounting sleeve 1.41 inch Rubber grommet 1.41 inch * not supplied with compressor Nut *
Compressor holding charge	Each compressor is shipped with a nominal dry nitrogen holding charge between 4 and 10 psi and is sealed with elastomer plugs. Before the suction and discharge plugs are removed, the nitrogen holding charge must be released via the suction schrader valve to avoid an oil mist blowout. Remove the suction plug	first and the discharge plug afterwards. The plug shall be removed only just before connecting the compressor to the installation in order to avoid moisture from entering the compressor. When the plugs are removed, it is essential to keep the compressor in an upright position so as to avoid oil spillage.
System cleanliness	The refrigerant compression system, regardless of the type of compressor used, will only provide high efficiency and good reliability, along with a long operating life, if the system contains solely the refrigerant and oil it was designed for. Any other substances within the system will not improve performance and, in most cases, will be highly detrimental to system operations. The presence of non-condensable substances and system contaminants, such as metal shavings, solder and flux, have a negative impact on compressor service life. Many of these contaminants are small enough to pass through a mesh screen and can cause considerable damage within a bearing assembly. The use of highly-hygroscopic polyester oil in SZ compressors requires that the oil be exposed to the atmosphere just as little as possible.	System contamination is one of main factors affecting equipment reliability and compressor service life. It is important therefore to take system cleanliness into account when assembline a refrigeration system. During the manufacturing process, circuit contamination may be caused by: • Brazing and welding oxides, • Filings and particles from the removal of burrs in pipe-work, • Brazing flux, • Moisture and air. Consequently, when building equipment and assemblies, the precautions listed in the following paragraphs must be taken.
Tubing	Only use clean and dehydrated refrigeration grade copper tubing. Tube cutting must be carried out so as not to deform the tubing roundness and to ensure that no foreign debris remains within the tubing. Only refrigerant-grade fittings should be used and these must be of	both a design and size to allow for a minimum pressure drop through the completed assembly. Follow the brazing instructions next pages. Never drill holes into parts of the pipe-works where fillings and particles can not be removed.
Brazing and soldering	Do not blend the compressor discharge or suction lines or force system piping into the compressor connections, because this will increase stresses that are a potential cause of	failure. Recommended brazing procedures and material, are described on following page. Never drill holes into parts of the pipe-works. Where fillings and particles can not be removed.

lanfos

Copper to copper connections	When brazing copper-to-copper connections, the use of a copper / phosphorus brazing alloy containing 5% silver or more with a melting	temperature of below 1472°F is recommended. No flux is required during brazing.
Dissimilar metals connection	When manipulating dissimilar metals such as copper and brass or steel, the use of silver solder and anti-oxidant flux is necessary.	
Compressor connection	When brazing the compressor fittings, do not overheat the compressor shell, which could severely damage certain internal components due to excessive heating. Use of a heat shield and/or a heat-absorbent compound is highly recommended. Due to the relatively sizable tubing and fitting diameters used for the large scroll, a double tipped torch using acetylene is recommended for the S240-300-380 brazing operation.	 the torch evenly around the joint, in applying only enough brazing material to flow the full circumference of the joint. Move the torch to Area C only long enough to draw the brazing material into the joint, but not into the compressor. Remove all remaining flux once the joint has been soldered with a wire brush or a wet cloth. Remaining flux would cause corrosion of the tubing. In addition, for discharge connections equipped with a non return valve integrated in discharge fitting (SY/SZ240-300) the direction of the

For rotolock version compressors, solder sleevestulare available. For brazing the suction andsudischarge connections, the following proceduresysis advised:• Make sure that no electrical wiring is connectedTh

to the compressor. • Protect the terminal box and compressor painted surfaces from torch heat damage (see diagram).

• Remove the teflon gaskets when brazing rotolock connectors with solder sleeves.

• Use only clean refrigeration-grade copper tubing and clean all connections.

• Use brazing material with a minimum of 5% silver content.

• Purge nitrogen or CO₂ through the compressor in order to prevent against oxidation and flammable conditions. The compressor should not be exposed to the open air for extended periods.

Use of a double-tipped torch is recommended.
Apply heat evenly to Area A until the brazing temperature is reached. Move the torch to Area B and apply heat evenly until the brazing temperature has been reached there as well, and then begin adding the brazing material. Move

In addition, for discharge connections equipped with a non return valve integrated in discharge fitting (SY/SZ240-300) the direction of the torch has to be as described on the picture, and maximum brazing time should be less than 2 minutes to avoid NRVI damages.

Ensure that no flux is allowed to enter into the tubing or compressor. Flux is acidic and can cause substantial d amage to the internal parts of the system and compressor.

The polyolester oil used in SY / SZ compressors is highly hygroscopic and will rapidly absorb moisture from the air. The compressor must therefore not be left open to the atmosphere for a long period of time. The compressor fitting plugs shall be removed just before brazing the compressor.

A Before eventual unbrazing the compressor or any system component, the refrigerant charge must be removed from both the high and low pressure sides. Failure to do so may result in serious personal injury. Pressure gauges must be used to ensure all pressures are at atmospheric level.

For more detailed information on the appropriate materials required for brazing or soldering, please contact the product manufacturer or distributor. For specific applications not covered herein, please contact Danfoss Commercial Compressors for further information.

Danfoss

Application guidelines	Installation			
System pressure test	Always use an inert gas such as nitrogen for pressure testing. Never use other gasses such as oxygen, dry air or acetylene as these may form	an inflammable mixture. Do not exceed the following pressures:		
	Maximum compressor test pressure (low side)	SM/SZ 084 - 185: 363 psig SY 240 to 380: 319 psig		
	Maximum compressor test pressure (high side)	464 psig		
	Maximum pressure difference between high and low side of the compressor:	348 psig		
	Pressurize the system on HP side first then LP side to prevent rotation of the scroll. Never let the pressure on LP side exceed the pressure on HP side with more than 72 psi. On SY/SZ240-300 models which have an internal non return-valve in discharge fitting	e or if an external non return valve is present on the discharge line, we advise to pressurize the system not quicker than 70 psi/s to allow enoug pressure equalisation between LP and HP side over the scroll elements.		
Leak detection	The compressor has been strength tested and leak proof tested (<3g/year) at the factory.Always use an inert gas such as Nitrogen or Helium	 Pressurize the system on HP side then LP side Do not exceed the test pressures indicated in the previous section "System pressure test" 		
Vacuum evacuation and moisture removal	 Moisture obstructs the proper functioning of the compressor and the refrigeration system. Air and moisture reduce service life and increase condensing pressure, and cause excessively high discharge temperatures, which can destroy the lubricating properties of the oil. Air and moisture also increase the risk of acid formation, giving rise to copper platting. All these phenomena can cause mechanical and electrical compressor failure. For these reasons it's important to perform a vacuum dehydration on the system to remove all residual moisture from the pipe-work after 	 < 100 ppm moisture level. The required moisture level in the circuit after vacuum dehydration must be < 100 ppm for systems with an SM / SY / SZ. Never use the compressor to evacuate the system. 		

Application guidelines	Installation	
Filter driers	A properly sized & type of drier is required. Important selection criteria include the driers water content capacity, the system refrigeration capacity and the system refrigerant charge. The drier must be able to reach and maintain a moisture level of 50 ppm end point dryness (EPD). For new installations with SM/SY/SZ compressors with polyolester oil, Danfoss recommends using the Danfoss DML (100% molecular sieve) solid core filter drier. Molecular sieve filter driers with loose beads from third party suppliers shall be avoided. For servicing of existing installations where acid formation is present the Danfoss DCL (solid core) filter driers containing activated alumina are recommended.	The drier is to be oversized rather than under sized. When selecting a drier, always take into account its capacity (water content capacity), the system refrigeration capacity and the system refrigerant charge. After burn out, remove & replace the liquid line filter drier and install a Danfoss type DAS burn-out drier of the appropriate capacity. Refer to the DAS drier instructions and technical information for correct use of the burnout drier on the liquid line. Also for new installations with SM compressors with mineral oil the Danfoss DCI drier is recommended.
Refrigerant charging	For the initial charge the compressor must not run and eventual service valves must be closed. Charge refrigerant as close as possible to the nominal system charge before starting the compressor. This initial charging operation must be done in liquid phase. The best location is on the liquid line between the condenser outlet and the filter drier. Then during commissioning, when needed, a complement of charge can be done in liquid phase: slowly throttling liquid in on the low pressure side as far away as possible from the compressor suction connection while compressor is running. The refrigerant charge quantity must be suitable for both summer and winter operations.	Vacuum or charge from one side can seal the scrolls and result in a non-starting compressor. When servicing, always ensure that LP/HP pressures are balanced before starting the compressor. Be sure to follow all government regulations regarding refrigerant reclamation and storage. For more detailed information, see "Recommended refrigerant system charging practice" news bulletin FRCC.EN.050.
Insulation resistance and dielectric strength	Insulation resistance must be higher than 1 megohm when measured with a 500 volt direct current megohm tester. Each compressor motor is tested at the factory with a high potential voltage (hi-pot) that exceeds the UL requirement both in potential and in duration. Leakage current is less than 5mA.	readings. Such readings do not indicate a faulty compressor. In testing insulation resistance, Danfoss recommends that the system be first operated briefly to distribute refrigerant throughout the system. Following this brief operation, retest the compressor for insulation resistance or current leakage.
	SM/SY/SZ scroll compressors are configured with the pump assembly at the top of the shell, and the motor below. As a result, the motor can be partially immersed in refrigerant and oil. The presence of refrigerant around the motor windings will result in lower resistance values to ground and higher leakage current	Never reset a breaker or replace a fuse without first checking for a ground fault (a short circuit to ground). Be alert for sounds of arcing inside the compressor.

Danfoss

Application guidelines	Installation			
Commissioning	The system must be monitored after initial start- up for a minimum of 60 minutes to ensure proper operating characteristics such as:	 Low foaming in sight glass and compressor sump temperature 18°F above saturation temperature to show that there is no refrigeran migration taking place, 		
	 Proper metering device operation and desired super heat readings, 	Acceptable cycling rate of compressors, including duration of run times,		
	 Suction and discharge pressure are within acceptable levels, 	• Current draw of individual compressors within acceptable values (max. operating current),		
	 Correct oil level in compressor sump indicating proper oil return, 	• No abnormal vibrations and noise.		
Oil level checking and top-up	In installations with good oil return and line runs up to 66 ft, no additional oil is required. If installations can be influenced by the pre-			
	installation lines exceed 66 ft, additional oil may be needed. 1 or 2% of the total system refrigerant charge (in weight) can be used to roughly define	refrigerant in the oil. Always use original Danfoss oil from new cans.		
	the required oil top-up quantity but in any case the oil charge has to be adjusted based on the oil level in the compressor sight glass.	Compressor seriesOilSMMineral oil 160PSYP.O.E. 320 SZ

Danfoss Commercial Compressors

is a worldwide manufacturer of compressors and condensing units for refrigeration and HVAC applications. With a wide range of high quality and innovative products we help your company to find the best possible energy efficient solution that respects the environment and reduces total life cycle costs.

We have 40 years of experience within the development of hermetic compressors which has brought us amongst the global leaders in our business, and positioned us as distinct variable speed technology specialists. Today we operate from engineering and manufacturing facilities spanning across three continents.

Our products can be found in a variety of applications such as rooftops, chillers, residential air conditioners, heatpumps, coldrooms, supermarkets, milk tank cooling and industrial cooling processes.
